STREAM EVALUATION MAP
STATE OF
NORTH DAKOTA

INTRODUCTION

Increasing demands for water throughout the West due to predicted development of energy and agricultural resources and attendant municipal/industrial growth may significantly impact existing fishery resources. This map provides information on which stream reaches may be further jeopardized by reduced or altered flows and diversions.

This stream evaluation map is provided to assist Federal and State agencies and water users in assessing the impact of proposed water development projects on existing fishery resources. The map covers the entire state of North Dakota and includes all streams within the State and is based on information and professional judgment of the State's Fish and Wildlife Department. This map will be reevaluated as new information is acquired.

Information depicted on the map is essential to identifying highly valued fish habitat and to maintaining existing fish populations and establishing instream flow requirements to maintain existing fisheries or other instream water uses.

This map was developed as a product of a cooperative effort whose participants included the U.S. Department of the Interior, Office of Biological Services and Division of Ecological Services, Bureau of Land Management; the State of North Dakota; and Colorado, Idaho, Montana, Nebraska, Nevada, North Dakota, South Dakota, Utah, Wyoming, and the U.S. Environmental Protection Agency. Funds for preparation and production of these maps were provided by the Federal Interagency Energy/Ecosystem Research and Development Program, Office of Energy, Minerals, and Industry, U.S. Environmental Protection Agency.

METHOD

A standard rating system was used by the State Fish and Wildlife Departments conducting the evaluation. Habitat evaluated by the rating system included perennial streams, their tributaries, intermittent streams, and streams that are or proposed to be under the Wild and Scenic Rivers Act. Intermittent streams that were not evaluated by the rating system but were identified as such were also evaluated. Information presented on this map originated from the State Fish and Wildlife Departments and is based on the rating system scheme with existing fishery habitat assigned one of four values.

VALUE CLASS	MAP CODE	CLASS DEFINITION
I	P	Highest-valued fishery resource
II	O	High-priority fishery resource
III	Y	Substantial fishery resource
IV	R	Limited fishery resource

To determine the appropriate value class, each stream reach was judged on criteria provided below. The final value classification assigned to the habitat was determined by the highest rating given to the habitat. The rating system allows for the possibility to upgrade or downgrade the overall habitat evaluations when the rating for criteria 1-3 was less than the highest possible rating.

1. Occurrence of State or Federal endangered species.
2. Occurrence of State or Federal threatened species.
3. Species of high interest to the State.
4. Habitat restoration, reclamation, or mitigation potential.

A value class was determined for each criterion as follows:

1. Status of State or Federal Endangered Species

Value Class I Documented occurrence (legally defined) of any State or Federally chartered endangered species.

Value Class II Probable occurrence of an endangered species based on documented occurrence of a species familiar with the stream reach. It is differentiated from Value Class I by the fact that undocumented occurrence of an endangered species is not available for the reach.

Value Class III Not applicable; only value classes I, II, and IV were used for Criterion 1.

Value Class IV Absence or no record of any endangered species.

2. Status of State or Federal Threatened Species

Value Class I Documented present occurrence of a State or Federally chartered threatened species.

Value Class II Documented past occurrence and probable continued existence of a threatened species.

Value Class III Possible occurrence of a threatened species.

Value Class IV Absence or no record of any threatened species.

3. Species of High Interest

Value Class I Habitat maintaining outstanding populations of species of high interest as defined by the State. To be considered high interest, a species must maintain a high yield or represent a unique aesthetic, scientific, economic, educational, or recreational value.

Value Class II Habitat that is intensively used in terms of several requirements of a highly-valued population. Habitat that maintains a relatively high-valued population of a species of high interest.

Value Class III Habitat that is occasionally used by a highly-valued population or high interest. Habitat that is maintained for maintenance, a relatively low-valued population of a species of high interest. Occasional use of habitat does not indicate that habitat would not seriously impair the continued existence of the population.

Value Class IV Habitat that is used sporadically or unpredictably used by species of high interest.

4. Habitat Restoration, Reclamation, or Mitigation Potential

Value Class I Very low or essentially no potential for restoration, reclamation, or mitigation of the stream segment. Compensation and population levels, no alternate resource could be introduced that would be acceptable to the user. Compensation options are available to compensate for the loss of this habitat. Compensation options for stream reaches that have been designated as habitat for reintroduction of an endangered species by a National Recovery Team or State Rehabilitation Plan.

Value Class II Low potential exists for either restoration, reclamation, or mitigation of the stream segment. Compensation and population levels, no alternate resource could be introduced that would be acceptable to the user. Compensation options are available to compensate for the loss of this habitat.

Value Class III Moderate potential exists for either restoration, reclamation, or mitigation of the stream segment. Compensation and population levels, no alternate resource could be introduced that would be acceptable to the user. Compensation options are available to compensate for the loss of this habitat.

Value Class IV Current technology makes it probable that the habitat can be restored or reclaimed to at least an equally valued fishery as that existing prior to development. Acceptable compensation options are likely.

For the reader interested in detailed documentation of the assigned value classification for North Dakota streams, this information can be requested at the following location:

Bismarck, North Dakota 58501

For the purposes of comprehensive planning and as a standard geographical framework for water and related land resources management, hydrologic units have been delineated by the U.S. Water Resources Council. These hydrologic units are outlined on the face of the map and are designated as follows:

Hydrologic Unit Base Map compiled, edited and published by the Geological Survey

in cooperation with the U.S. Water Resources Council

1977 North American Datum

Datum is mean sea level
